

Sample questions for midterm

Note that these are not all questions – there will also be some true/false questions and questions that test your understanding.

1. You have an object type "candy" with three attributes: ID, name, and weight of a piece. You have an object type "wrapper" with three attributes: wrapper ID, paper type, paper color. Define a table "candy_to_sell" that holds following information about candy: candy price in one column, candy itself in the second column, and wrapper information in the third column. Write a query that would obtain information about wrapper objects from this table (assume there is some information in it) as whole objects!
2. Define the object type for candy with following attributes: weight of one piece, and the name! Define subtype for the candy! The subtype is 'gummy candy' with additional attributes: candy color and Boolean attribute that holds information on whether candy is made from natural juice!
3. Create a materialized view based on the schema you see below so that it would update as soon as new information is inserted in tables, and so that it would enable query rewrite! The materialized view should store item name and revenue obtained from selling this item (i.e., two columns). [SCHEMA GIVEN]
4. Create a data model with MODEL clause based on the table below. Assume that the combination of Year, City, Month and Furniture type is unique. Your created model should update the maintenance cost for all the months of 2023 by 10%. [SCHEMA GIVEN]
